

Going to Extremes: Politics after Financial Crises, 1870-2014

Manuel Funke* Moritz Schularick§ Christoph Trebesch¶

December 7, 2015[‡]

Abstract

Partisan conflict and policy uncertainty are frequently invoked as factors contributing to slow post-crisis recoveries. Recent events in Europe provide ample evidence that the political aftershocks of financial crises can be severe. In this paper we study the political fall-out from systemic financial crises over the past 140 years. We construct a new long-run dataset covering 20 advanced economies and more than 800 general elections. Our key finding is that policy uncertainty rises strongly after financial crises as government majorities shrink and polarization rises. After a crisis, voters seem to be particularly attracted to the political rhetoric of the extreme right, which often attributes blame to minorities or foreigners. On average, far-right parties increase their vote share by 30% after a financial crisis. Importantly, we do not observe similar political dynamics in normal recessions or after severe macroeconomic shocks that are not financial in nature.

1 Introduction

With the catastrophe of the 1930s in mind, the fear of political radicalization in the wake of economic and financial disasters looms large in public discourse. Recent events in the Eurozone support such concerns. Since 2008, two-party systems that were stable for decades were swept away in the wake of the economic and financial turmoil. New political forces have since entered parliament and gained ground, while others have disappeared from the political map. In many countries, parties on the extreme right such as Front National in France or Golden Dawn in Greece have scored major electoral successes. Populist or openly Eurosceptic parties such as the Five Star Movement in Italy, Podemos, the party of True Finns, the UK Independence Party, or the Alternative for Germany have been surprise winners in recent elections.

Increasing fractionalization and polarization of parliaments makes crisis resolution more difficult, reduces the chances of serious reform and leads to political conflict at a time when decisive political action may be needed most. A number of authors have linked political gridlock to slow recoveries from financial crises. Frieden (2015), Mian, Sufrin, and Trebbi (2014) as well as Lo and Rogoff (2015) argued that dysfunctional politics contribute to the now well documented phenomenon of slow recoveries from financial crises (Jordà, Schularick, and Taylor 2013, 2014b).¹ These ideas complement an important body of work in macroeconomics in recent years that has studied policy uncertainty and its economic effects in more depth (Bloom, Bond, and Van Reenen 2007; Bloom 2009; Bloom et al. 2012; Bachmann, Elstner, and Sims 2013; Baker, Bloom, and Davis 2013). An important insight resulting from this literature is that measured policy uncertainty is particularly high after financial crises. However, with few exceptions, there is limited empirical evidence on the underlying channels.²

What has history to say about the political after-effects of financial crises in modern democracies? Can we, over the long-run of modern history, identify systematic shifts in

¹Polarization and fractionalization may also have longer-term repercussions on the political economy. For example, Alesina and Tabellini (1990) and Azzimonti (2011) predict that more polarized political systems produce economic inefficiencies, higher debt, and lower growth. Alt and Lassen (2006), Lindqvist and Östling (2010), Azzimonti and Talbert (2014) and Azzimonti (2015) provide empirical evidence supporting this view.

²An exception here are Baker et al. (2014) who show that political polarization was an important driver for the increase in US policy uncertainty since the 1960s.

voting behavior after financial crises? And if so, in which direction? Does the extreme left or the extreme right gain, or both? To answer these questions, we examined the political aftermath of all major financial crises in advanced economies since the late 19th century. We also assembled the most ambitious and comprehensive historical dataset of election results and parliamentary composition to date, covering 20 countries and spanning 140 years with more than 800 elections between 1870 and 2014.

Our first key finding is that financial crises are followed by important changes in voter behavior that in turn, contribute to high levels of policy uncertainty. Political polarization increases after financial crises throughout the 19th and 20th century. Moreover, political parties on the far right appear to be the biggest political beneficiaries of a financial crash. On average, far-right parties have seen an increase in their vote shares of about 30% relative to their pre-crisis level in the five years following a systemic financial crisis. These findings echo a recent study by de Bromhead, Eichengreen, and O’Rourke (2012), who focus on the electoral consequences of crises in the 1920s and 1930s. We show that the gains of far-right parties were not limited to the interwar period: In recent decades, far-right parties, including populist parties of the so-called “New Right”, also saw broad-based electoral gains. After financial crises, voters seem to be systematically lured by the political rhetoric of the far right, with its frequently nationalistic or xenophobic tendencies. Moreover, we identify an important asymmetry in the political response to crises: on average, the far left did not profit equally from episodes of financial instability.³

Our second main insight is that governing becomes more difficult after financial crises, irrespective of which parties are in power. In particular, *after* World War II, crises are associated with shrinking government majorities, a strengthening of opposition and greater political fractionalization. This in turn is associated with a higher probability of government crises and changes in the executive branch. We thus confirm the finding of Mian, Sufi, and Trebbi (2014) that political fractionalization increases in the aftermath of financial crises after 1980. However, using the depth of our historical dataset we can show that these effects have become stronger over time.

Third, we document that street protests increase dramatically in the aftermath of finan-

³This finding somewhat contradicts Giuliano and Spilimbergo (2014) who link recession experiences to distrust in institutions, leading to more right voting, as well as to more support of government intervention/redistribution, resulting in more left voting.

cial crises. Riots, strikes and demonstrations can be seen as an additional proxy for political constraints on governing. Passarelli and Tabellini (2013) have recently demonstrated how social unrest may negatively impact policy-making in democracies.

Generally, our study suggests that policy-making and the implementation of reforms become substantially more difficult in the aftermath of a financial crisis. These results are robust to controlling for macroeconomic and financial conditions as well as political factors such as electoral systems, voter turnout, suffrage and different government systems.

On the methodological side, we use the statistical toolkit of local projections (LPs) pioneered in Jordà (2005) and project the path of political variables over a five and ten year horizon following the beginning of a financial crisis recession. As in Jordà, Schularick, and Taylor (2013; 2014a; 2014b), we compare the political aftermath of crisis recessions to the aftermath of (non-financial) recessions. We find that the political effects of financial crises are particularly more pronounced than those of normal recessions that tend to have little or no effects on political variables.

A potential concern with these findings is that financial recessions could be deeper than normal recessions and as a result the observed effects are due to the severity of the recession and not to the financial crisis. In the spirit of Barro and Ursúa (2008), we then compare financial crisis recessions to other severe macroeconomic “disasters” that do not involve a financial crash. We find that the effects are much more pronounced in financial crises and conclude that financial crashes stand out since their political after-effects are particularly disruptive.

What explains the more severe political fall-out after financial crises? One possibility is that non-financial downturns are seen as “excusable” events, triggered by exogenous shocks, while financial crises may be perceived as endogenous and “inexcusable” – the result of policy failures, moral hazard and favoritism. The electorate may blame politics for financial crashes because the perception is that they could have been avoided. Moreover, financial crises may provoke unprecedented policy reactions and uncertainty about their consequences, which in turn reduces confidence in the political leadership. Financial crises may also have social repercussions that are not observable after non-financial recessions. For example, it is possible that the disputes between creditors and debtors are more severe or that inequality rises more strongly (e.g., Bordo and Meissner 2011). Lastly, financial

crises involve unpopular bailouts for the financial sector (e.g., Broz 2005), which increases political discontent.

On the data side, a core contribution of this paper is the compilation of a rich new dataset that will benefit future research in the field. Our newly compiled data covers the near universe of systemic financial crises and general elections in 20 advanced economies since 1870. Since financial crises are rare events, many researchers in this field have opted to go back in time and use longer time spans of data to study crises and their consequences (e.g., Reinhart and Rogoff 2009a, 2009b, 2015; Schularick and Taylor 2012; Perri and Steinberg 2012; Kose, Loungani, and Terrones 2013; Jordà, Schularick, and Taylor 2013, 2014a; 2014b). We focus on advanced economies and intentionally avoid blending the experience of developing and advanced economies. We study systemic banking crises only and avoid less precise definitions of financial crises that, to varying degrees, encapsulate inflation spurts, stock market crashes, currency crashes and sovereign defaults. For the coding of systemic banking crises, we rely on the papers by Jordà, Schularick, and Taylor (2013; 2014a).

This paper is part of a growing literature on the political consequences of financial crises. The majority of existing studies focus on individual countries or shorter time windows.⁴ An exception is Chwioroth and Walter (2013) who study leadership turnover during and after banking crises in 20 developed and developing countries since 1830.⁵ Our analysis differs from these previous studies in that we focus on political responses to economic crises in a broad sense, and not only on government survival or leadership turnover.⁶ We are aware of only one paper with a similar focus, namely that of Mian, Sufi, and Trebbi (2014). Moreover, we are the first to study the link between crises and social unrest for a

⁴See Eichengreen (1992); Haggard (2000); MacIntyre (2002); Bernhard and Leblang (2008); Crespo-Tenorio, Jensen, and Rosas (2012); de Bromhead, Eichengreen, and O'Rourke (2012).

⁵They use the Reinhart and Rogoff (2009b) crises dating and follow the approach by Crespo-Tenorio, Jensen, and Rosas (2012) to measure political turnover risks. Their main result is that governments are more likely to lose power following a financial crisis today, compared with during the 19th or early 20th century. Their interpretation is that citizens' awareness of the ability of the government to manage the economy increased dramatically in the wake of the Great Depression and World War II. Another recent long-run analysis is by Ahlquist, Anselly, and Lindvall (2014), who find that the political cost of exiting a fixed exchange rate regime is high, both before and after World War II.

⁶Specifically, we consider the vote share of government coalitions regardless of whether they were the government that led the country into the crisis or were the one that replaced it. We are not mainly interested in the (somewhat unsurprising) punishment of poor economic policy-making and crisis management by incumbent governments, but in the general ability of a country to establish political stability and leadership in the aftermath of a financial crisis.

broad cross-country dataset, which corroborates Ponticelli and Voth’s (2011) analysis of the political effects of austerity policy.

The structure of the paper is as follows. In the next section we introduce our dataset; in the third section we discuss the statistical design. The fourth section contains the empirical core of our study: we demonstrate the electoral successes of far-right parties, the increase in political polarization and fragmentation, and its link to instability and uncertainty. In the fifth section we compare financial crises to severe and normal non-financial recessions as well as to other macro disasters. The last section of this paper concludes and summarizes our findings.

2 Data

In this study, we draw on a broad set of historical data. This section describes the main variables used in our analysis, all measured at annual frequency and for the following 20 developed economies: Australia, Austria, Belgium, Canada, Denmark, Finland, France, Germany, Greece, Ireland, Italy, Japan, the Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, the United Kingdom and the United States. Appendix Table [A1](#) lists the definitions and sources for our main variables, and Appendix Table [A2](#) shows the summary statistics.

2.1 Election results and parliamentary composition, 1870-2014

We compiled an archive of 827 parliamentary elections from throughout history. This new dataset, encompassing the years from 1870-2014, includes detailed information on general elections to the national parliaments of the 20 countries in our sample. Presidential elections, non-nationwide (regional or local) elections and referendums are excluded. In case of two or more elections in one year (e.g., Greece in 2012), we count the last election in that year. In the case of bicameral legislatures (e.g., in the United States), only elections to the *lower* chamber are considered (e.g., the US House of Representatives). Altogether, we identified 859 elections, but could not find sufficient data for 32 of these. Therefore, the final sample includes 827 election events.⁷ Appendix Table [B1](#) gives an overview of which parliamentary

⁷Another reason for missing data were institutional factors. In the 19th century, some parliaments consisted merely of unlinked, nonpartisan candidates from various constituencies. It was therefore not

elections we coded and shows the names of the respective parliaments/chambers as well as cases with missing data. The information on vote shares and on the distribution of seats in parliament come from three main sources, namely Döring and Manow (2012), Mackie and Rose (1974) and Nohlen and Stöver (2010). In addition, we drew on a series of country-specific sources, which are also listed in Appendix B.

Based on the raw data, we group the vote shares along several dimensions. First, we add together votes of anti-system parties, i.e., *vote shares of parties on the far left or the far right*, which seek to change the system of government per se (see Sartori 1976). To categorize parties as far-right or far-left we follow de Bromhead, Eichengreen, and O’Rourke (2012) for the interwar period (1919-1938). Extremist parties in the pre-1919 period are ignored, simply because there are no sufficient sources for a clean classification. For the period after 1939, we track the parties coded as extremist by De Bromhead, Eichengreen, and O’Rourke (2012), and their follow-up or splinter formations. Furthermore, we identify newly formed parties on the extreme left and right by assessing the political platform of each party gaining more than 0.1% of the vote in our post-World War II sample of elections. For this purpose we draw on Betz (1994), Ignazi (2003), Minkenberg (1998; 2001; 2008), Minkenberg and Perrineau (2007), Mudde (2000; 2005; 2007), country reports by Bertelsmann Stiftung (2009), as well as large number of country-specific sources listed in Appendix B.

In the spectrum of far-right parties, we include parties of the “New Right”, i.e., those parties in the grey area between far-right extremism and right-wing populism. This follows the widespread view in political science literature that the profile of the political far right has undergone fundamental changes since World War II (e.g., Betz 1994; Ignazi 2003). Many parties discarded openly fascist and anti-democratic attitudes and adopted a more moderate tone in reference to ethnocentrism, nationalism and secessionism, most recently often combined with a Eurosceptic platform. On the far left, we include all parties that take up traditional communist and/or Marxist-Leninist positions. Similar to the right wing views, we also include parties that would not be identified as communists in the traditional

possible to assign members to parties and to compute vote and seat shares. This was the case in the Dutch general elections from 1871-1887 (Mackie and Rose 1974, p. 267), the Norwegian parliamentary elections 1870-1879 (Rokkan 1967, p. 376) and the Swedish general elections from 1872-1884 (Stjernquist 1966, p. 120).

sense, but included those who refuse contemporary international economic order and base their national economic policies on an anti-capitalist ideology (e.g., “The Left” in Germany). Some of these parties can also be classified in the populist, Eurosceptic spectrum. For example, we code the “United Left” in Spain and the Italian anti-establishment party “Five Star Movement” as far-left parties. Appendix Table B2 provides further details and shows all parties classified as far-right and far-left in our sample.

Second, we add up the *government vote share* by combining the votes of the governing party or of parties in the governing coalition, as well as the *opposition vote share*, which is done by combining the vote share of all parties in the opposition. This was possible to do for most countries since 1870, although we exclude elections in monarchies in the early years of the sample, i.e., of the German Reich, Denmark, Finland (under Russian occupation), Japan, Norway, Portugal, Spain and Sweden. We also exclude elections in the fascist and military dictatorships of Germany (1933-1945), Italy (1924-1945), and Portugal (1926-1974).⁸ The distinction between government and opposition does not make much sense for these countries during those time periods. We again refer to Appendix Table B1, which gives a condensed overview of the elections in our sample and their characteristics.

To identify government and opposition we draw on a wide range of sources, in particular Döring und Manow (2012), as well as a series of country-specific sources listed in Appendix B. In parliamentary systems, we code those parties that were represented in the cabinet as government parties. In presidential systems, we code only the president’s party as the government party, while all remaining parties are coded as opposition parties. We exclude independent candidates without party affiliation, since they may switch sides depending on the law that is under consideration (this follows Mian, Sufi, and Trebbi 2014). If there is a change in power in a given year, we code the vote shares of the newly elected government, not of the outgoing one.⁹

Lastly, we code two measures on the degree of parliamentary fragmentation based on the raw data on seats in parliament.¹⁰ First, we simply count the *number of parties in*

⁸There were no elections in Spain from 1936-1974 and in Greece from 1937-1941 and from 1967-1973.

⁹Whenever government formation after an election exceeds the turn of a calendar year (e.g., in the United States) we record the year in which the election took place. In cases of interim governments we denote the next partisan government that took office.

¹⁰To go as far back as possible, these measures are computed for all elections, except for the elections held during the dictatorships in Germany from 1933-1945, in Italy from 1924-1945, and in Portugal from 1926-1974. In other words, we explicitly include monarchies with a legislature. However, the results are

parliament. Second, we consider the distribution of parliamentary seats among parties following the more sophisticated approach implemented by Beck et al. (2001). Specifically, we code a long-run measure of *fractionalization*, which is defined as the probability that two representatives picked at random from among the parties in the legislature will be of different parties. More formally this can be written as:

$$legislative\,fractionalization = 1 - \sum_{i=1}^n \left[\frac{(n_i - 1) \frac{n_i}{N}}{N - 1} \right] ,$$

where n = number of parties, n_i = seats held by the n -th party, and N = total seats in the parliament. Of course, in this context of course the definition of “party” is crucial. See Appendix B for details on the coding of this variable. The fractionalization measure is bound between 0 and 1. The lowest value of 0 indicates no fractionalization, while the value of 1 indicates maximal fractionalization.

2.2 Street protests, 1919-2012

In addition to the parliamentary variables, street protests are good indicators of political radicalization and serve as a proxy for political instability in the post-crisis period (see, for example, Ponticelli and Voth 2011; Passarelli and Tabellini 2013). To approximate street protest we rely on the dataset of Banks and Wilson (2014), which provides information on the annual frequency of domestic conflict events from 1919 to 2012 (excluding the World War II period from 1940 to 1945). In particular, we consider the number of *general strikes*, defined as “any strike of 1,000 or more industrial or service workers that involves more than one employer and that is aimed at national government policies”, the number of *violent riots*, defined as “any violent demonstration or clash of more than 100 citizens involving the use of physical force”, and the number of *anti-government demonstrations*, defined as “any peaceful public gathering of at least 100 people for the primary purpose of displaying or voicing their opposition to government policies”. We use the sum of these three variables as our baseline variable – termed *street protests* – to measure the overall degree of open protest in the street.

In comparison to our other dependent variables, street protests show strong time trends, also robust to when monarchies are excluded.

which is evident when looking at Figure C1 in the appendix. The degree of social unrest is very volatile and can double from one decade to another; our data shows peaks during the 1960s and 2010s. At the same time, there is on average long periods with little street protest, e.g. the 1980s and 1990s. To deal with time trends in the data, we decomposed the variable into a trend and cycle component. Specifically, we apply the widely used Hodrick Prescott filter (see Hodrick and Prescott 1997) with a smoothing parameter of 6.25. Using it as dependent variable, we then compute the percent deviation from trend for the street protest variable. This reduces the risk of spurious inference, but also makes the results somewhat harder to interpret.

2.3 Financial crises and recessions

Financial crises are defined as events during which a country’s banking sector experiences bank runs, sharp increases in default rates accompanied by large losses of capital that result in public intervention, bankruptcy, or forced merger of financial institutions.¹¹ Dates of systemic financial crises are based on the study by Jordà, Schularick, and Taylor (2013), which build on the timing of historical crisis events pioneered by Bordo et al. (2001) and Reinhart and Rogoff (2009b). The Laeven and Valencia (2008, 2012) dataset of systemic banking crises is the main source for post-1970 crisis events. Appendix Table D1 shows a full list of the 103 financial crises in our dataset.

Besides financial crisis dates, we also determine the dates of recessions following the data and methodology in Jordà, Schularick, and Taylor (2013). Specifically, we generate two auxiliary dummy variables using the intuition in the Bry and Boschan (1971) algorithm to capture business cycle features in the data. This algorithm separately generates dates of peaks and troughs in economic activity for each country in our sample. Using real GDP per capita, a peak corresponds to a local maximum and a trough corresponds to a local minimum. A recession is defined as the period between a peak and the following trough, whereas an expansion is defined as the period between the trough and the subsequent peak.

For the empirical analysis, we then make the distinction between recessions that coincide with a major financial crisis – termed *financial crisis recessions* – and those

¹¹Jordà, Schularick, and Taylor (2014a) emphasize the distinction between isolated banking failures (such as the demise of Baring Brothers in the U.K. in 1995) and systemic distress (such as the Global Financial Crisis 2008). However, their systemic financial crisis classification has proven valuable in previous studies.

without major financial disruptions – termed *normal recessions*. More precisely, we call a recession *financial* if a major financial crisis erupts within a two year window around the peak of the cycle. Appendix Table D2 shows the full list of financial and normal recessions in our dataset. Benchmarking normal vs. financial recessions allows for cleaner identification of the effects of financial crises rather than comparing financial crises spells to a counterfactual of all other years. However, normal recessions are typically less severe than financial recessions. Therefore, as a second benchmarking exercise, we also compare financial recessions to a subset of normal recessions that are particularly deep. In the spirit of Barro (2006) and Barro and Ursúa (2008; 2011), we term these severe normal recessions as *non-financial macro disasters*. Specifically, we keep only those non-financial recessions with an average GDP p.c. decline that is higher than the *average* GDP decline during financial recessions. We apply this cut-off separately for the pre-World II sample (with a threshold of 3.35%) and for the post-World War II sample (with a threshold of -2.55%). The end result is a list of non-financial macro disasters provided in Appendix Table D3. On average, these events see a GDP contraction of 5.82% per year. The results are similar if we use a full-sample average, or if we use the median GDP contraction as a cut-off. Similarly, the results are roughly the same if we apply an even stricter threshold and only consider the worst 25% normal recessions (those with the highest GDP contractions).

3 Statistical design

For each dependent variable, we start with a preliminary view of the data, including summary statistics, visual plots of the data and OLS panel regressions. We then take the time dimension more seriously and estimate local projections (LPs) following the method pioneered by Jordà (2005) and applied in a range of closely related studies (Jordà, Schularick and Taylor 2011; 2013; 2014a). Moreover, we provide a range of robustness checks of our estimates.

In a first step, we compare pre-crisis spells with post-crisis spells following Mian, Sufi, and Trebbi (2014). Specifically, we restrict the sample to a full five years before and a full five years after a financial crisis, excluding the crisis year itself. In cases of follow-up crises, where the five year pre-crisis horizon and the five year post-crisis horizon overlap,

we exclude subsequent crises as we interpret them as after-effects of the initial crisis. Note that crises where either the crisis event itself or one of the five year windows coincides with years of global wartime (1914-1918 and 1939-1949) are omitted from the sample. We again refer to Appendix Table D1, which also indicates the 67 (of 103) crises that are considered in the descriptive analysis.

In step two, we then expand the analysis to more broadly compare crisis times to non-crisis times, by running fixed effects panel OLS regressions in our full sample. This allows us to tease out post-crisis deviations from the long-run historical average, using more than 100 years of data. Specifically, we start with a ‘bare bones’ model in which our dependent variables, i.e., election results and parliamentary composition (denoted as Y_{it}), are regressed on a post-crisis indicator variable $post_{it}$ that takes the value of 1 in the five years after a crisis event τ . We only add country fixed effects μ_i to account for unobservable country-specific heterogeneity. This simple model can be written as follows:

$$Y_{it} = \alpha + \beta * post_{it} + \mu_i + \varepsilon_{it}$$

$$where\ post_{it} = \{\tau_i + 1, ..., \tau_i + 5\}. \quad (1)$$

Different from the descriptive analysis, however, we do not restrict the post-crisis spell to a full five years. Post-crisis years now include all years within (i.e., up to) five years after a financial crisis event. Again, Table D1 indicates the 94 (of 103) crises included in the baseline OLS regression. We again remove follow-up crises and crises that began during global wartime.¹²

Third, we follow Jordà (2005) and calculate dynamic multipliers. There are several advantages to this approach, which explains its growing popularity. Local projections handle asymmetries, non-linearities, and richer data structures with great ease. We follow Jordà, Schularick, and Taylor (2013) and distinguish between *financial recessions* and those without major financial disruptions, i.e. *normal recessions*. The reasoning behind it is that financial crises often go hand in hand with economic recessions. One could therefore argue that the changes in the political environment that a country experiences after a financial

¹²Note that Spain and Switzerland experienced a financial crises in 1913. These crises are technically not excluded, but their entire coincides with World War I.

crisis are mainly a function of the recession and independent of the financial crisis *per se*. Therefore, a stricter test for the effects of financial instability on politics is not based on a comparison of financial crisis periods with tranquil times when the economy expands, but it compares financial crises to recession periods, including severe recessions (or macro disasters).

The first type of recession is associated with a financial crisis. The second type is a standard business cycle contraction without a systemic financial event. This results in a chronology of business cycle peaks, where “N” denotes a non-financial business cycle peak, and “F” denotes a peak associated with a systemic financial crisis. Table D2 in the appendix shows the dates of financial crisis recessions and “normal”, non-financial recessions in each country. The list of recessions in that table includes the subsample of particularly severe non-financial recessions (macro disasters), which are shown again separately in Table D3 and are defined above. Note that we again exclude any years of global wartime (1914-1918 and 1939-1949) in the analysis.

The fixed-effect regressions discussed above resemble unconditional averaging in the sense of a basic event-study approach à la Romer and Romer (1989) in which every occurrence is treated identically. Yet such an approach may not provide sufficient economic structure as economies are complex and dynamic systems. In the local projection set-up we control for observable macroeconomic factors that might impact the post-crisis trajectory of a country. As a proxy for overall economic conditions, we include the growth rate of real GDP per capita as well CPI inflation. However, we also tested the robustness of our results with additional variables such as loan growth and public debt.¹³ The long-run data comes from the macroeconomic database compiled by Jordà, Schularick, and Taylor (2013).¹⁴ By controlling for economic factors with more variables and more complex dynamics, we make it far less likely that financial crises *per se* are an independent driver of political reactions and not a function of economic conditions.

Our *treatment* variables will simply be the occurrence of a financial or normal recession (including non-financial macro disasters). Clearly, the term *treatment* does not necessarily have to be interpreted in a causal sense. The notation works as follows. N and T denote

¹³This, however, did not significantly affect our main results and our sample often shrank considerably.

¹⁴For a more detailed documentation of their sources, please refer to their study directly.

the cross-sectional and time dimension of the panel. Y_{it} is a vector of political and macroeconomic variables. For any variable we want to estimate the change in that variable from the beginning of the recession (previous peak) at time t to time $t + h$.

We will calculate this response by estimating a fixed-effects panel model with a discrete treatment depending on whether the recession is financial or not (N, F):

$$\begin{aligned} \Delta_h y_{it+h}^k &= \alpha_i^k + \theta_N^k N + \theta_F^k F + \\ &+ \sum_{j=0}^p \Gamma_j^k Y_{it-j} + u_{it}^k; \quad k = 1, \dots, K; \quad h = 1, \dots, H \end{aligned} \quad (2)$$

where θ_N^k is the *normal* recession treatment ($N = 1$)¹⁵ and θ_F^k is the *financial* recession treatment ($F = 1$). In addition, lags of the control variables Y at time t are included, as are α_i^k country fixed effects; also u is the error term.

4 Going to extremes: politics after financial crises

In this section we present and discuss the historical evidence that the political climate changes substantially after financial crises leading to greater political instability and uncertainty. More specifically, we will present three main stylized facts from 140 years of modern political economy. First, politics take a “hard right turn” after financial crises. Both before *and* after World War II, we observe a significant increase of votes for far-right parties. In contrast, parties on the far left of the political spectrum did not have comparable electoral successes after crises. Second, we also find that political polarization increases substantially after financial crises as measured by weaker government majorities, a stronger opposition and a greater fractionalization of parliaments. These effects are considerably more pronounced after World War II than before. Finally, we show that street protests typically increase after financial crises, then and now.

¹⁵In the more restrictive benchmarking exercise with non-financial macro disasters, we only consider those non-financial business cycle peaks “N” that are followed by particularly deep recessions (see above) and set milder recessions to zero.

4.1 Increasing polarization: hard right turns

A striking result of our election coding effort is the strong evidence for the rise of extremist parties in the aftermath of financial crisis, in particular for far-right parties. This is true for both before and after World War II. Starting with some simple descriptive statistics, Figure 1 shows average vote shares of far-left and far-right political parties five years before and five years after financial crisis events between 1919 and 2014.¹⁶ Far-right voting increases from about 6% to about 10% of the vote following a financial crisis. In contrast, we do not observe a strong post-crisis increase in far-left voting.

Figure 1: Vote shares of the far right and left

Notes: The figure shows average vote shares of far-left (white columns) and far-right (black columns) political parties. The grey columns represent the sum of the two. The left panel refers to average vote shares in the five years before the start of a financial crisis and the right panel shows average shares in the five years after. The differences are statistically significant at the 5% level, except for the far-left vote share, which does not significantly increase in the post-crisis period. Table D1 shows the crises included.

4.1.1 Some historical narrative

The electoral gains of far-right parties have been particularly pronounced after the global economic crises of the 1920s/1930s and after 2008. In the interwar period, the most prominent cases are Italy and Germany. Mussolini's fascist alliance benefited from the early 1920s banking crisis in Italy and the global recession after the end of World War I,

¹⁶We exclude crises that erupt within less than five years after a preceding crises as well as crises where either the pre-crisis or post-crisis overlaps with a period of global wartime (see data section above).

earning 19.1% of the vote in 1921 and about 65% in 1925. In Germany, the Nazis won 18.3% of the vote in the 1930 elections, more than 30% in the two 1932 elections, and over 40% in the March 1933 elections, when the Great Depression had its strongest impact on Central Europe. However, during the 1930s far-right parties also had increased electoral success in Belgium (the Rexists and the Flemish National Union), Denmark (the National Socialist Workers' Party), in Finland (Patriotic People's Movement), in Spain (Falange) and in Switzerland (National Front).

In the aftermath of the 2007-08 global crisis, far-right and right-wing populist parties more than doubled their vote share in many advanced economies, including France, the UK, Sweden, Finland, the Netherlands, Portugal and Japan. For example, the Sweden Democrats improved their vote share from 2.9% in 2006 to 5.7% in 2010. In the Netherlands, the right-wing populist Party for Freedom gained almost 10 percentage points following the 2007 crisis (5.9% in 2006 vs. 15.5% in 2010). In France, the Front National party earned 13.6% in 2011, in the first election following the crisis, compared to just 4.3% in 2007. Similarly, we find that the vote share of the True Finns party skyrocketed from 4.1% in 2007 to 19.1% in 2011.

These patterns can also be seen when using supplementary data from elections to the European Parliament in 2004, 2009, and 2014. Due to the short history of the European parliament, this data is not used in the remainder of the paper, but they are illustrative of the trends observed above, also because the electoral rules and voting dates are the same for all EU countries. As we show in Figure 2, the vote share of far-right parties increased in the majority of countries over time, with an especially strong spike between the 2009 and 2014 elections in the wake of the European financial crisis. Among the countries in our sample, the largest electoral gains were made by the Front National party in France. UKIP in the United Kingdom and the Danish People's Party also showed massive gains in the 2014 elections. On average, the far-right vote share approximately tripled between 2004 and 2014.

Importantly, however, the observed shift to the right is not only a phenomenon of the "Great Depression" of the 1930s and the "Great Recession" of the late 2000s. As we will illustrate below, our results hold even when these two significant episodes are excluded. Indeed, hard right turns are also observed following more regional financial crisis events, for

Figure 2: Far-right and right-wing populist votes in European elections

Notes: The figure shows the vote shares of far-right and right-wing populist parties in the elections to the European Parliament 2004, 2009, and 2014. These 9 EU countries are also included in the main analysis. The figure is for illustration only, since electoral data from the European Parliament are not used in the remainder of the paper. The grey columns show averages.

instance the late 1980s/early 1990s Scandinavian banking crisis. In Norway, the right-wing populist Norwegian Progress Party won just 3.7% of the vote in 1985. In 1989, in the first election after the financial crisis of 1987, the same party won 13% of the vote and became the third political force. Also its Danish counterpart, the Danish Progress Party, more than doubled vote shares from 3.6% in 1984 to 9% in 1989, becoming the fifth political force in the first election after the crisis. Prior to the Swedish financial crisis of 1990, right-wing parties earned below 1% of the vote in the 1988 election. However, after the crisis, in 1991, they won 6.8% of the vote. The newly founded right-wing populist party “New Democracy” gained an impromptu 25 parliamentary seats.¹⁷

¹⁷Other examples include the 1991 financial crisis and subsequent economic stagnation in Switzerland, where the Swiss People’s Party achieved about 11% of the vote during the 1980s, and then improved its vote share to 15% in 1995 and then to 22.5% in 1999. During this same period, the 1990 Italian financial crisis was followed by the sudden rise of the federalist and right-wing populist North League party. This party increased its vote share from just 1.3% in the 1987 elections to 8.7% in the post-crisis elections of 1992 and was a relevant political force throughout the 1990s. More generally, we found that one in three far-right political parties was established following a financial crisis (ten-year window).

4.1.2 Empirical results

These anecdotal observations are strengthened by the results of fixed-effects panel regressions of vote shares on a post-crisis dummy variable (which has the value of 1 for the five years following a financial crisis). To tease out the vote share deviation from the long run historical average, we include all non-crisis years. Table 1 shows the regression results for the full sample (left panel), the interwar period (middle panel) and the post-World War II period (right panel).

Table 1: Far-right and far-left vote shares: post-crisis years vs. normal years

	(a) Full sample	(b) Pre-WWII	(c) Post-WWII
Far-right vote share			
Post-crisis	4.212* (2.174)	3.288 (3.461)	3.770*** (1.098)
R^2	0.023	0.012	0.056
Obs.	1611	390	1221
Far-left vote share			
Post-crisis	-1.580 (0.984)	-0.001 (0.344)	0.437 (1.034)
R^2	0.015	0.000	0.001
Obs.	1611	390	1221

Notes: This table compares the post-crisis levels of far-right and far-left vote shares to their average level. The time window for post crisis is five years. Robust standard errors (clustered by country) are shown in parentheses. The results are similar when controlling for economic fundamentals, such as the growth rate of GDP per capita and the CPI inflation rate (not reported). The left panel covers the years 1919-2014, excluding World War II, the middle panels 1919-1938, and the right panels 1950-2014. Table D1 shows the crises included. *** Significant at .01. ** Significant at .05. * Significant at .1.

Far-right votes increase by more than 4 percentage points after financial crises in the full sample. This difference is significant at the 10% level. In the post-World War II sample we find a significant (at the 1% level) increase of 3.8 percentage points in right-wing voting. The coefficient for the period between 1919-1938 is comparably large but not statistically significant. The interwar increase in extremist voting is partly driven by two of the 20 advanced countries in our sample, Germany and Italy, while the post-crisis shift to the far

right after World War II is a more widespread phenomenon. Accordingly, once we remove the country fixed effects, we find a significant coefficient of 5.3 for far-right votes after crises in the pre-World War II sample.

Figure 3 shows local projections of the cumulative change in far-right vote shares for years 1–5 of the financial recession (red line), controlling for real GDP growth and inflation (and their lags). The shaded region is a 90% confidence interval. Analogous to the OLS regressions, we show results in the full sample with all recessions (left panel), pre-World War II recessions (middle panel) and post-World War II recessions (right panel). The figure points to a constant upward trend in far-right voting after financial recessions in the full sample, and both before and after World War II. The same can be seen in the corresponding results in Table 5 in the text below. On average, far-right votes increase by more than 30% (not percentage points) in the five years after financial recessions.

Figure 3: Far-right vote shares (local projections): financial crisis recessions

Notes: Each path shows local projections of the cumulative change relative to peak for years 1–5 of the recession/recovery period. The red line refers to the average path in financial crisis recessions and the shaded region is a 90% confidence interval. The controls are contemporaneous and 1-year lagged values of the growth rate of GDP per capita and the CPI inflation rate at peak. The left panel covers the years 1919-2014, excluding World War II, the middle panel 1919-1938, and the right panel 1950-2014. Table D2 shows the recessions included. The dependent variable is the combined vote share of all electorally successful far-right political parties in the most recent general election. For the corresponding regression results see Table 5 in the text below.

These results are robust when we exclude the dictatorship spells from the pre-World War II sample in Austria and Germany from 1933-1938 and in Italy from 1924-1938 (Spain had no elections during the rule of Franco). Second, the results also hold when we remove the Great Depression and the 2007-08 global financial crisis from the sample.

We also tested the robustness of our results by controlling for additional characteristics of each election and of the country’s voting system, in particular voter turnout (by election, in %), suffrage (population eligible to vote, by election, in %), a dummy for presidential vs. parliamentary system and a dummy for proportional representation vs. first-past-the-post system.¹⁸ The latter measures are important, since presidential democracies and those with first-past-the-post voting systems typically have a less fragmented legislature and tend towards a two-party system (e.g., Lijphart 1994; Horowitz 2009), which could bias our results. However, none of the additional control variables changed our results on far-right voting in a meaningful way.

As an additional test, we divide the group of far-right parties into those of the “Old Right” and those of the “New Right” (see chapter 2.1). We find that the postwar results are mainly driven by the latter, meaning that right-wing populist parties benefited more than traditional fascist and neo-Nazi parties of the extreme right. Nevertheless, traditional far-right parties also see increased vote shares after financial crises in the postwar period; it is just not as pronounced as it is for the populist “New Right” parties such as the UKIP or the Dutch Freedom Party.

Finally, it is clear that in terms of ideology politics has many more dimensions than our classification as “far-left” or “far-right”. Therefore, we applied our statistical analysis to a more narrow and a more wide dimension of politics. More specifically, following Döring and Manow (2012), we classified (post-World War II) political parties into “anti-EU” versus “pro-EU” platforms (as a narrow dimension) as well as into “libertarian” versus “authoritarian” platforms (as a broad dimension). The results however were not straightforward in both cases, suggesting that “far-left” versus “far-right” was a reasonable choice.

4.2 Increasing fragmentation: governing becomes more difficult

In the next part of our analysis, we focus on the measures of political fragmentation and the strength of government outlined above. Figure 4 shows kernel density estimates

¹⁸The data on voter turnout and suffrage comes from the same sources as our electoral data (see appendix). To classify systems of government (parliamentary vs. presidential) we use Banks and Wilson (2014). Information on the history of European and Anglo-Saxon voting systems before 1980 was obtained from McLaren Carstairs (1980) and Lijphart (1994), respectively. All coding after 1980 follows Beck et al. (2001).

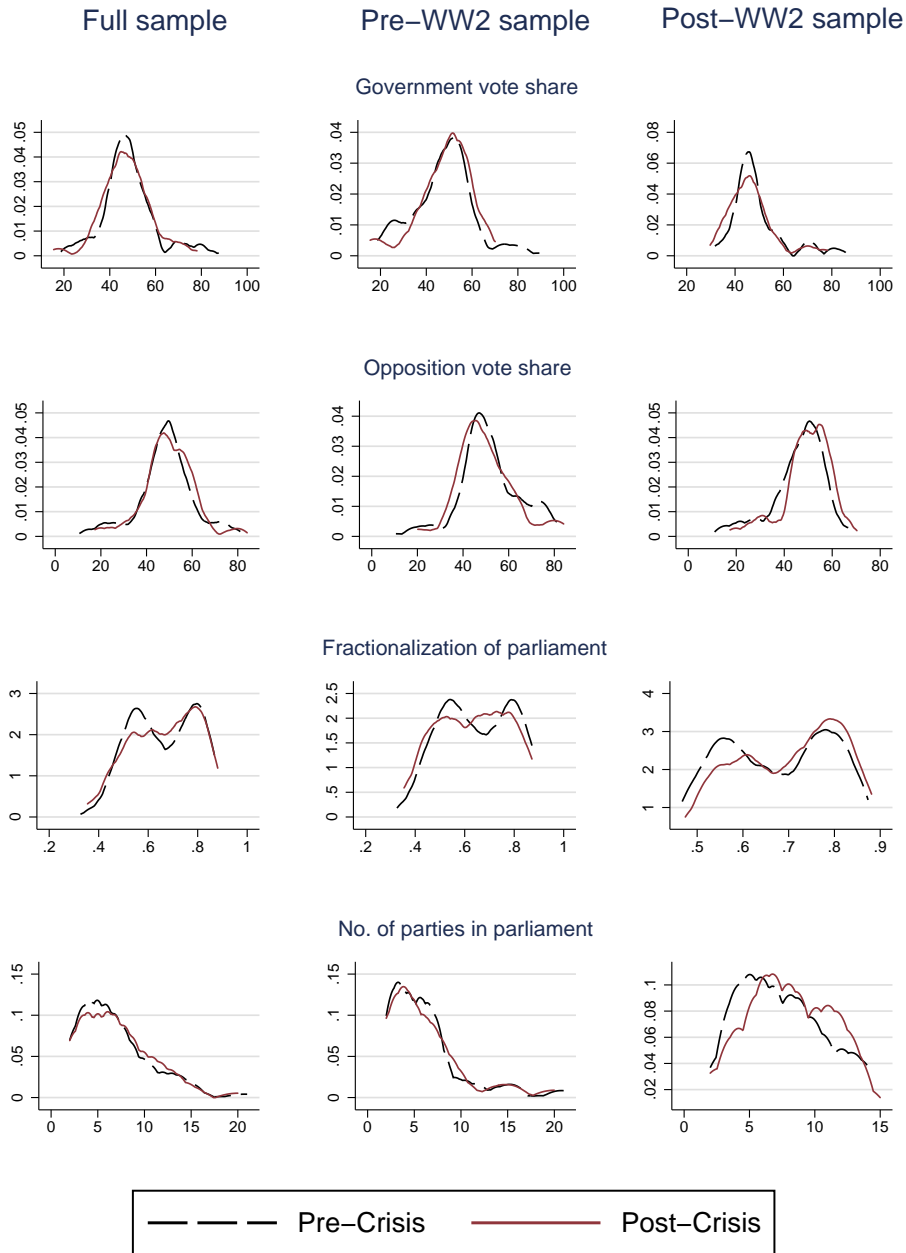

of government vote shares, opposition vote shares, our measure on the fractionalization of parliament, and the number of parties in parliament (horizontal panels). Again, we distinguish between the full sample of crises, pre-World War II crises, and post-World War II crises (vertical panels). For each variable, we show kernel densities for the five years prior to a financial crisis (black line) and the five years afterwards (red line).

The figure suggests notable changes in the political response to crises over the past 140 years. In the contemporaneous sample (after World War II), overall fractionalization increases, the number of parties in parliament grows, governments appear weaker, and opposition forces strengthen (in terms of vote shares) after a financial crisis relative to before the crisis. In contrast, the picture is less clear in the pre-World War II period, at times even moving in the opposite direction with regard to government support and opposition forces. Similarly, both parliamentary fractionalization and the number of parties seem to decline post-crisis rather than increasing. Thus, it seems that the weakening of governing coalitions and the fractionalization of parliaments after crises is a relatively recent phenomenon.

4.2.1 Historical evidence

There are many examples for weakening government support and a fragmentation of parliament following financial crises in the post-World War II era. Most notably, the global crisis of 2008 saw a general decline in voter support for the governing coalition and for big tent parties. This was true, for example, in Belgium, Denmark, Germany, Japan, the Netherlands and Portugal, where voter's support for the governing party or coalition decreased by up to 20 percentage points between the last election before the crisis until the first election afterwards. In Spain, for instance, the two main parties that had been alternating power for decades, the People's Party and the Socialist Workers' Party, saw their joint vote share decline from 83.8% in 2008 to just 73.4% in 2011 and similar developments could be observed in France and Germany. In Sweden, the centre-right alliance turned from a majority government in the 2006 election to a minority government in the 2010 election. In the United Kingdom, the Conservatives achieved only 47% of the seats in 2010, which resulted in a hung parliament and a coalition government with the Liberal Democrats, the second such arrangement in British history (the only other

Figure 4: Kernel densities of parliamentary variables

Notes: The figure shows kernel densities of four different parliamentary variables (illustrated by each row of panels). The black dashed line refers to the five years before a financial crisis and the red line to the five years after a financial crisis. The left panels cover crises in the years 1870-2014, the middle panels 1870-1938, and the right panels 1950-2014. Periods of global war (1914-1918 and 1939-1949) are excluded. Table D1 details which crises are included.

coalition government was formed in 1974). Also the Scandinavian banking crisis of the late 1980s and early 1990s was followed by minority governments and weaker governing

coalitions, for example the Norwegian cabinet of Jan Syse in the 1989 elections and the Danish government of Poul Schlüter in 1990.

We also find numerous instances of new parties rising and entering parliament in the aftermath of financial crises. In Spain, the number of parties in parliament increased from 10 to 13 in 2011, and two newly founded parties, “Podemos” and “Ciudadanos” are gaining ground, with strong regional and local election results in recent years. In the Italian 2013 elections, a new anti-establishment party named the “Five Star Movement” earned 108 parliamentary seats and 25.5% of the vote off the cuff, posing a threat to effective governing. Further examples include the Swedish “New Democracy”, which was founded and entered parliament after the country’s banking crisis of 1990, and Italy’s “North League” which won 55 seats in the first election after the outbreak of the 1990 crisis.¹⁹

There are a few such anecdotes when we go further back in history. Interesting cases include several English-speaking countries during the 1930s, which saw many more parties entering parliament in response to the economic and financial turmoil brought about by the Great Depression. In Australia, the “Emergency Committee of South Australia” arose, winning six parliamentary seats in its first and only contested election in 1931. In Canada, the “Reconstruction Party” and the “Social Credit Party”, both founded in 1935, entered parliament instantly. Similarly, in the United States, the populist “Wisconsin Progressive Party”, won seven seats in its first contested election in 1934. Moreover, in the United Kingdom, the “Independent Labour Party” broke away from Labour while the “National Liberal Party” broke away from the Liberals before the 1931 elections, both over disagreements on how to respond to the severe economic problems of the time. Taken together, these examples illustrate that financial crises have often been followed by notable shifts in the political system.

¹⁹Similarly, during the mid 1970s crisis in Britain, the separatist parties from Wales (Plaid Cymru) and Scotland (Scottish National Party) entered parliament for the first time. In Japan, the financial crisis of the 1990s was followed by significant changes in the party spectrum, which had been very stable in the preceding decades. In the four elections between 1990 to 2000, six new parties entered parliament, most notably the “New Frontier Party” (156 seats in 1996) and the “Democratic Party of Japan” (52 seats in 1996). The latter won a landslide victory in 2009 and replaced the Liberal Democratic Party, which had been in power almost uninterruptedly since 1955.

4.2.2 Empirical results

Fixed-effects OLS regressions corroborate the impression given by the kernel density estimates and the anecdotal evidence presented above. The results from Table 2 are particularly pronounced for the post-World War II period. Government vote shares drop by close to 4.4 percentage points, while the opposition vote share increases by 3.5 percentage points. This compares to a mean value of 51% and 46%, respectively.²⁰ In contrast, in the pre-World War II period, the vote shares are statistically insignificant and show much smaller coefficients. The same is true when using the full sample.

The differences before and after the mid-20th century are also apparent for our fractionalization measures. Parliamentary fractionalization increases significantly, by more than 6 percentage points in the contemporaneous sample, but it is not affected after financial crises prior to World War II (coefficient not significant). Similarly, we find that the coefficient for the number of parties in parliament is large and significant after World War II, but not before. The point estimate of 1.11 indicates that, on average, more than one additional party entered the legislature in the five-year spell after financial crises since 1950.

The results are strengthened when estimating local projections and controlling for macroeconomic fundamentals, as shown in Figure 5. In the full sample and for the pre-World War II sample, the results show no significant dynamics. The indicators for financial recessions are mostly insignificant (see also the Appendix Tables E1 to E4). However, in the post World War II sample, government vote shares drop significantly after financial recessions and opposition vote shares increase, particularly in years 2 and 3 after the recession start.²¹

With respect to fractionalization, the results are equally pronounced. The two lower panels of Figure 5 show that both the fractionalization and the number of parties in the legislature increase significantly in the aftermath of financial recessions after World War II. Parliamentary fractionalization rises by 1.6%, cumulatively, over a five year horizon,

²⁰The discrepancy in coefficient size between government and opposition vote shares indicates that previously unaligned factions join the opposition in post-crisis periods.

²¹The coefficients indicate that governments saw their vote shares drop by a cumulative 9% (not percentage points) in the immediate aftermath of financial crises in the post-World War II era. The second panel shows the corresponding result for opposition vote shares, which increase by a total of 11% in year 2 after the start of the recession and the cumulative effect remains significant with a high coefficient until the five year horizon.

Notes: This table compares the post-crisis levels of the parliamentary variables to their average levels. The time window for post crisis is five years. Robust standard errors (clustered by country) are shown in parentheses. Table D1 details which crises are included. The results are similar when controlling for economic fundamentals, such as the growth rate of GDP per capita and the CPI inflation rate (not reported). The left panels cover the years 1870-2014, the middle panels 1870-1938, and the right panels 1950-2014. Periods of global war (1914-1918 and 1939-1949) are excluded. *** Significant at .01. ** Significant at .05. * Significant at .1.

while the increase in the number of parties amounts to almost 10% in year 5. As discussed above, the results in this section are also robust when controlling for voter turnout, suffrage, presidential vs. parliamentary systems and for proportional representation vs. first-past-the-post systems (see above for definition and sources).

A potential explanation for the stronger effects post-World War II is that the share of “economic voters” has grown in the wake of the Great Depression and World War II. This interpretation is in line with Chwioroth and Walter (2013), who argue that citizen’s

Figure 5: Parliamentary variables (local projections): financial crisis recessions

Notes: Each path shows local projections of the cumulative change relative to peak for years 1–5 of the recession/recovery period. The red line refers to the average path in financial crisis recessions and the shaded region is a 90% confidence interval. The controls are contemporaneous and 1-year lagged values of the growth rate of GDP per capita and the CPI inflation rate at peak. The left panels cover the years 1870–2014, the middle panels 1870–1938, and the right panels 1950–2014. The periods of global war (1914–1918 and 1939–1949) are excluded. Table D2 shows the recessions included. For the corresponding regression results refer to Appendix Table E1 (government vote share) up through Table E4 (number of parties).

awareness of the ability of the governments to handle economic problems has increased strongly over the past century. Moreover, it is likely that increasing democratization after World War II brought more and more extra-parliamentary protest and “special issues”

into the political system. The growth of protest parties is largely a post-World War II phenomenon too. Clearly, for the pre-World War I period, data availability is also a constraint.

4.2.3 Polarization, instability, and uncertainty

What are the consequences of increased polarization and fractionalization after financial crises? To address this question, we study the links between polarization and policy uncertainty and instability. In particular, we want to understand whether political instability increases in years with weaker governments and more fragmented parliaments.

A useful proxy for political stability in the post-crisis period is the number of major government crises per year, defined as “any rapidly developing situation that threatens to bring the downfall of the present regime” by Banks and Wilson (2014). To approximate political instability and uncertainty, we also use a dummy on executive turnover from the Gloemans, Gleditsch, and Chiozza (2009) *Archigos* dataset. Here a year in which “a new executive leader-spell begins” is coded as 1, and all other years as zero.²² Table 3 displays the results of fixed-effects regressions.

The dependent variables are a) government crises and b) executive turnover, and the sample is restricted to a five year window post-crisis as in Mian, Sufi and Trebbi (2014). The regression for government crises uses a standard fixed-effects OLS model (column 1), since there are up to six government crises in a single year. The regressions with executive turnover as dependent variable use a fixed effects logit model (column 2), since turnover is binary, but the results are similar with OLS. Both models include year and country fixed effects.

These exploratory regressions show that the more strongly polarized politics seen after financial crises tend to be associated with more frequent government instability and a higher probability of executive turnover. For instance, a one standard deviation (14.5%) drop in the government vote share is associated with a 0.31, or approximately half a standard deviation, increase in the number of severe government crises in post-crisis years, on average. Similarly, a one standard deviation increase in fractionalization (by 0.18)

²²Gloemans, Gleditsch, and Chiozza (2009) regard the prime minister as the chief executive in parliamentary systems, and in presidential systems, the president. We exclude executive turnovers that involve foreign imposition, assassinations, ill health, natural death or suicide.

Table 3: Political instability in the post-crisis period

	Major Government crises (Fixed effects OLS)	Executive turnover (Fixed effects logit)
Government vote	-0.0216* (0.0111)	-0.0701*** (0.0207)
R^2	0.301	-
Observations	235	249
Opposition vote	0.0213* (0.0116)	0.0670*** (0.0195)
R^2	0.302	-
Observations	235	249
Fractionalization	2.1268*** (0.6783)	3.7292** (1.4695)
R^2	0.315	-
Observations	252	380
No. of parties	0.0653** (0.0258)	0.0711 (0.0735)
R^2	0.229	-
Observations	252	380

Notes: This table regresses two measures of political instability (major government crises per year and a dummy for executive turnover) on our main parliamentary variables. The sample is restricted to five year post-crisis windows. Column 1 shows coefficients of an OLS regression with country and year fixed effects. Column 2 shows coefficients from a fixed effects logit regression. Robust standard errors in parentheses. *** Significant at .01. ** Significant at .05. * Significant at .1.

is associated with an increase in government crises by 0.38. The coefficients for vote shares and fractionalization in column 2 (executive turnover) are also quantitatively and statistically significant. Generally, the evidence uncovered here lends support to the idea that heightened political fractionalization and polarization after financial crises has negative effects, in particular on political stability.

An additional approach to gauge political (in)stability is to focus on “veto players” – a prominent concept in the political science literature advanced by Tsebelis (2002). A veto player is defined as a political actor who can veto reforms, i.e., who can stop a change from the status quo. The resulting *Veto Player Index* measures the number of such veto players and their ideological distance from each other. More details are discussed in Appendix F, which also shows results using the Veto Player Index as dependent variable. The bottom

line is that the power of veto players intensifies substantially (the index increases by nearly 40% within two years after the crisis outbreak). This result is in line with our interpretation above that policy-making and the implementation of reforms becomes substantially more difficult in the aftermath of a financial crisis.

4.3 People take to the streets

The recent turmoil in Europe’s troubled southern periphery, particularly Greece and Spain, has shown how a financial crisis can trigger political protest not only at the polls, but also in the streets. In this section, we study the link between crises and social unrest based on our long-run cross-country dataset.

Figure 6: Street protests

Notes: The figure shows the average number of street protest incidents per year, including the number of general strikes (light blue columns), violent riots (black columns), anti-government demonstrations (white columns) and the sum of the three (grey columns). The left panel refers to pre-crisis averages (five years) and the right-hand side bars to post-crisis averages (five years). Appendix Table D1 shows the crises that are included.

Figure 6 shows the average yearly number of general strikes (light blue columns), violent riots (white columns) and anti-government demonstrations (black columns). The grey columns sum these three components to an aggregate measure of street protests. We also consider the 1919-2012 period, which is the largest,²³ include our sample of 20 countries and compare five pre-crisis years (left panel) to five post-crisis years (right panel).

²³Domestic conflict event data is available from Banks and Wilson (2014) until 2012.

Table 4: Street protest variables: post-crisis years vs. normal years

	(a)Full sample	(b)Pre-WWII	(c)Post-WWII

Street protests			
Post-crisis	0.115** (0.045)	0.159** (0.070)	0.159** (0.071)
R^2	0.020	0.127	0.025
Obs.	1623	396	1227

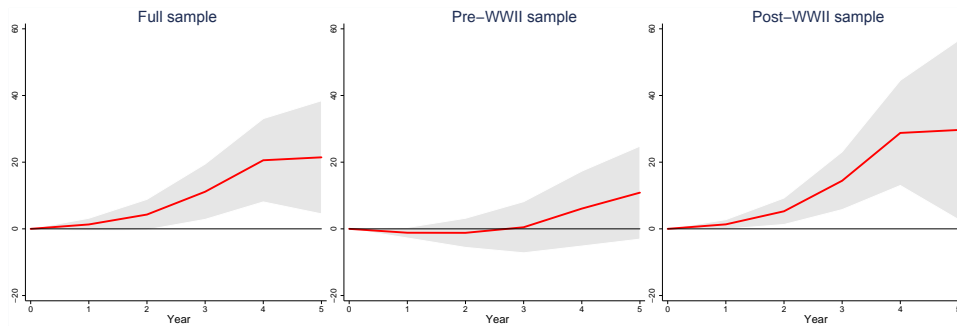

Notes: This table compares the post-crisis levels of the number of street protests events per year (% deviation from trend) to their average level. The time window for post crisis is five years. Robust standard errors (clustered by country) are shown in parentheses. Table D1 shows the crises that are included. Regressions controlled for GDP per capita growth rate and CPI inflation rate (not reported). The left panels cover the years 1919-2012, excluding World War II (1939-1949), the middle panels 1919-1938, and the right panels 1950-2012. *** Significant at .01. ** Significant at .05. * Significant at .1.

The figure indicates a strong increase in street protests in the crisis aftermath: the average number of incidents more than doubles during financial crises episodes, from about 1.2 events to just under 3 per year, and this difference is statistically significant at the 5% level. Looking at the different components, the average number of anti-government demonstrations almost triples, the average number of violent riots doubles, and general strikes increase by at least one-third. For demonstrations and violent riots, the mean difference is also statistically significant at the 5% level.

The fixed effects OLS regressions shown in Table 4 use the “detrended” street protest

measures as dependent variables and regresses the cyclical components on a five year post-crisis dummy. The results reinforce the impression of the descriptive picture above. Street protests see a significant increase post-crisis, both then and now, although the results vary by type of measure and the time sample used. General strikes and anti-government demonstrations increase most notably in crises after World War II, but see no significant increase in crises during the interwar period. The opposite holds true for violent riots, where the post-crisis dummy is significant at the 10% level before World War II, but not thereafter.

Figure 7: Streets protests (local projections): financial crisis recessions (% dev. from trend)

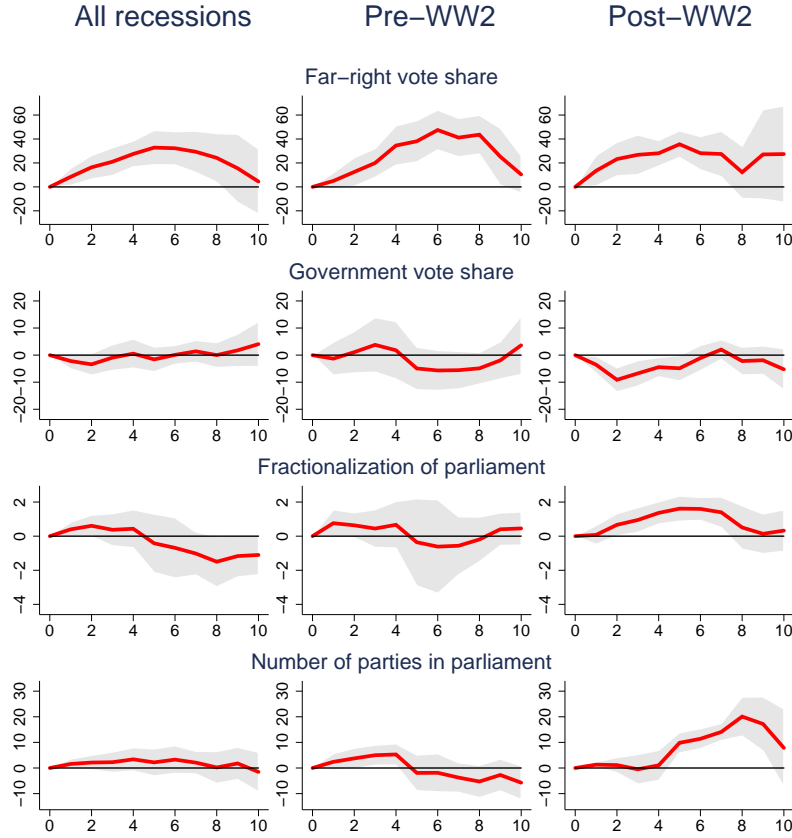

Notes: Each path shows local projections of the cumulative change relative to peak for years 1–5 of the recession/recovery period. The red line refers to the average path in financial crisis recessions and the shaded region is a 90% confidence interval. The controls are contemporaneous and 1-year lagged values of the growth rate of GDP per capita and the CPI inflation rate at peak. The left panel covers the years 1919–2014, excluding World War II (1939–1949), the middle panel 1919–1938, and the right panel 1950–2014. Table D2 shows the recessions that are included. The dependent variable is the percentage deviation from trend in the combined number of street protests (general strikes, violent riots and anti-government demonstrations) per year. For the corresponding regression results see Appendix Table E5.

The local projections in Figure 7 confirm these findings. We present the results for total street protest incidences, i.e., the combined number of general strikes, violent riots and anti-government demonstrations per year as the dependent variable. The picture looks similar if we use these variables individually. Street protests increase strongly in our full sample of financial crisis spells (left panel), with a cumulative deviation from trend of 20%. The results are more pronounced for the post-World War II sample (right panel), especially when compared to the pre-World War II sample (middle panel). This may be due to the fact that the frequency of street protests was generally high during the 1920s and 1930s.

4.4 How persistent are the effects?

How long-lasting are the political after-shocks of financial crises? Do the effects fade out, and if so, when? To shed light on this, we extend the time frame of the analysis to a ten year window after the crisis event. Figure 8 displays the post-crisis path of far-right and government vote shares as well as parliamentary fractionalization and the number of parties in parliament over a 10 year horizon.

Figure 8: 10-year local projections: financial crisis recessions

Notes: Each path shows local projections of the cumulative change in the political variables relative to peak for years 1–10 of the recession/recovery period. The red line refers to the average path in financial crisis recessions and the shaded region is a 90% confidence interval. The controls are contemporaneous and 1-year lagged values of the growth rate of GDP per capita and the CPI inflation rate at peak. Table D2 shows the financial crisis recessions included. Time periods for each variable are the same as in the above local projections of that variable in Section 4. For the corresponding regression results for years 1–5 we again refer to Table 5 (far-right vote share) in the text and to Table E1 (government vote share) up through Table E4 (number of parties) in the appendix. The regression results for years 6–10 are not reported, but are available upon request.

The graphs demonstrate that the political effects are temporary and diminish over time. 10 years after the crisis, almost all variables are back to their pre-crisis levels.

The top panel shows that the increase in far-right votes is no longer significantly different from zero after year 8. Also the point estimates decrease strongly from a peak of about 30% to 40% in year 5 to about 20% or less by year 10. We find similar responses when looking at government vote shares, as shown in the second panel of Figure 8. The point estimates decrease in years 6 to 10 after the crisis and are no longer different from zero in the medium and long run. The degree of political radicalization clearly diminishes over time. Parliamentary fractionalization measures also return to their initial levels over a 10 year horizon. Among all variables, the increase in the number of parties represented in parliament appears to be the most persistent effect of crises. In the post-World War II sample, it takes a decade before the effects are no longer visible in the data.

To sum up, the political consequences of financial crisis start to fade about 5 years after the beginning of the crisis. While some political after-effects of financial crises are measurable for a decade, the good news from our regressions is that the political upheaval in the wake of financial crises is mostly temporary.

5 Normal recessions and non-financial macro disasters

We have shown that financial crises go hand in hand with substantial radicalization and fragmentation of the political landscape. In this section, we compare the political fall-out from financial crises with other episodes of economic distress. It is by now a well-documented fact that financial crises are typically accompanied by economic recessions. Are the political after-effects of financial crises comparable to the political dynamics in other recessions, or are financial crises special? This is the first question we will address. A sceptic observer might point out that financial crisis recessions tend to be deeper than normal recessions so that the correct benchmark for comparison would be equally severe (non-financial) recessions. A second test is to compare the political aftermath of financial crisis with severe non-financial recessions — sometimes dubbed macro-disasters in the literature.

In the following section we track the trajectory of key indicators of political stability

Table 5: Local projections of far-right vote shares

(a) Full sample	Year 1	Year 2	Year 3	Year 4	Year 5
Financial recession	8.47* (4.34)	15.90** (5.97)	21.27*** (6.95)	27.85*** (6.38)	33.10*** (8.70)

Notes: *** Significant at .01. ** Significant at .05. * Significant at .1. Robust standard errors (clustered by country) in parentheses. Results correspond to local projections of cumulative change in 100 times the logged variable relative to peak for years 1–5 of the financial recession (first row), normal recession (second row), and non-financial macro disaster (third row). The top panel (a) covers the years 1919–2014, with World War II years (1939–1949) being excluded, the middle panel (b) covers the years 1919–1938, and the bottom panel (c) covers the years 1950–2014. Financial = normal (disaster) tests the null that coefficients for each type of recession are the same for the intercept terms in the first and second (third) rows. In each case the p-value of the test is provided. The controls are contemporaneous and 1-year lagged values of the growth rate of GDP per capita and the CPI inflation rate at peak (coefficients not reported). See text.

in financial crisis recession, in normal recessions and in deep economic crises that are not associated with a financial crash (“non-financial macro disasters”). We define the latter in Section 2 as (non-financial) recessions that are more severe than the average financial crisis recession, i.e., the annualized percentage fall in GDP per capita exceeds the respective thresholds of 3.35% (pre-World War II sample) and 2.55% (post-World War II sample). Financial crisis recessions are all recessions that coincide with a systemic financial crisis. All other recessions are called “normal recessions”. Consequently, in the local projections we will subject the economy to three different “treatments”: recessions associated with a systemic financial crisis, normal recessions, and other (non-financial) macro disasters.

Table 5 demonstrates that financial crises are different. Financial recessions are followed by a significantly larger increase in far-right votes than either normal recessions or non-financial macro-disasters. The F-test rejects the null of equal coefficients at most horizons. The only exception is the interwar period, where substantial increases in far-right votes also occurred in other recessions.

Table 6 shows the coefficients for the three types of downturns for the other political variables. To save space we exclude opposition vote shares and focus on the post-World War II sample where the effects are more precisely estimated. The full set of results can be found in Appendix Tables E1 up through E5. We also refer the reader to these tables for the R^2 and other test statistics.

What are the main insights from Table 6? First, in normal recessions, the political system remains relatively stable. Government vote shares and measures of parliamentary fragmentation do not see notable shifts. Similarly, street protests barely increase in the course of normal recessions. Second, a key difference between financial recessions and severe macro disasters is that support for the government increases during non-financial macro-disasters, but falls significantly in financial crisis recessions. Put differently, in non-financial disasters people rally behind the government. In financial crises, support for the government drops sharply. The bottom panel of Table 6 mirrors this finding: street protests rise strongly after financial crises, but stay flat in non-financial macro disasters. Parliamentary fragmentation increases after non-financial macro disasters, but the effects are estimated imprecisely and remain insignificant at all horizons.

To provide further robustness checks, we applied stricter thresholds to define macro-

Table 6: Local projections of political variables, post-World War II sample

disasters. For instance, we only coded the most severe non-financial recessions (top 25% and top 10% of the distribution) as macro disasters, or used the harshest non-financial recession in each country. None of this affected our core finding that the political fall-out from financial crises is different and, for the most part, more severe.

How can we account for the fact that financial crises provoke severe political disruptions and other economic crises do not? A first potential explanation could be that non-financial crises are perceived as “excusable” events, triggered by large exogenous shocks such as oil prices, natural catastrophes, or wars. In contrast, financial crises may be perceived as an endogenous and “inexcusable” types of crisis that are the result of policy failures, moral hazard and favoritism. In other words, the electorate may blame politics for the occurrence of financial crises because the perception is that the crash could have been avoided.

A second important explanation is that financial crises trigger unprecedented policy responses.²⁴ As there tends to be a large degree of uncertainty about the consequences of these policies, confidence in the political leadership may erode and increase the willingness to reject conventional policies. This in turn can give rise to populist or extremist views at the political fringe.

A third explanation is that financial crises typically involve bailouts for the financial sector and these are highly unpopular (e.g., Broz 2005). Consequently, financial crises may result in more political dissatisfaction than non-financial crises.²⁵

A fourth explanation is that financial crises have social repercussions that are not observable after non-financial recessions. For example, it is possible that the disputes between creditors and debtors are uglier in the wake of financial crises, be it internally or internationally (e.g., Halac and Schmukler 2004; Mian, Sufi, and Trebbi 2014). Similarly, it is possible that inequality rises more strongly in the aftermath of financial crises, but less so in other crisis types (e.g., Atkinson and Morelli 2011; Bordo and Meissner 2011). Exploring these questions in more detail is beyond the scope of this paper, but will be addressed in future research.

²⁴We are grateful to Eric Leeper for pointing this out.

²⁵These explanations relate to Giuliano and Spilimbergo (2014) who find a higher propensity to distrust political institutions among individuals growing up during recessions than among individuals without such experiences.

6 Conclusion

This paper studies the political aftermath of financial crises with a historical perspective. The evidence we uncover shows that financial crises put a strain on modern democracies. The typical political reaction is as follows: votes for far-right parties increase strongly, government majorities shrink, the fractionalization of parliaments rises and the overall number of parties represented in parliament jumps. These developments likely hinder crisis resolution and contribute to political gridlock. The resulting policy uncertainty may contribute to the much debated slow economic recoveries from financial crises.

Financial crises are politically disruptive, even when compared to other economic crises. Indeed, we find no (or only slight) political effects of normal recessions and different responses in severe crises not involving a financial crash. In the latter, right wing votes do not increase as strongly and people rally behind the government. In the light of modern history, political radicalization, declining government majorities and increasing street protests appear to be the hallmark of financial crises. As a consequence, regulators and central bankers carry a big responsibility for political stability when overseeing financial markets. Preventing financial crises also means reducing the probability of a political disaster.

Appendix A Variables and summary statistics

Table A1: Main variables: description and sources

Variable	Description	Sources
Government vote share	Vote share of governing party or coalition in the most recent general elections to the national parliament (lower chamber)	Mackie and Rose (1974), Nohlen and Stöver (2010), Döring and Manow (2012) and country-specific sources listed in Appendix B
Opposition vote share	Combined vote share of all opposition parties, excluding independents, in the most recent general elections to the national parliament (lower chamber)	Mackie and Rose (1974), Nohlen and Stöver (2010), Döring and Manow (2012) and country-specific sources listed in Appendix B
Far-right/ far-left vote share	Combined vote share of all far-right (far-left) political parties with more than 0.1 % of total votes in the most recent general elections to the national parliament (lower chamber)	Bertelsmann Foundation (2009), Betz (1994), Capoccia (2012), de Bromhead, Eichengreen, and O'Rourke (2012), Minkenberg, (2001, 2008), Mudde (2000, 2005, 2007) and country-specific sources listed in Appendix B
Fractionalization	The probability that two representatives picked at random from among the parties in the legislature will be of different parties; range: [0;1]	Mackie and Rose (1974), Nohlen and Stöver (2010), Döring and Manow (2012) and country-specific sources listed in Appendix B
No. of parties	The number of parties elected into the legislative branch in the most recent general election to the national parliament (lower chamber)	Mackie and Rose (1974), Nohlen and Stöver (2010), Döring and Manow (2012) and country-specific sources listed in Appendix B
Violent riots	Any violent demonstration or clash of more than 100 citizens involving the use of physical force.	Banks and Wilson (2014)
General strikes	Any strike of 1,000 or more industrial or service workers that involves more than one employer and is aimed at national government policies or authority	Banks and Wilson (2014)
Demonstrations	Any peaceful public gathering of at least 100 people for the purpose of voicing opposition to government policies or authority, excluding demonstrations of a distinctly anti-foreign nature	Banks and Wilson (2014)
Street protests	The sum of violent riots, general strikes, and demonstrations per year	Banks and Wilson (2014)
Executive turnover	1 indicates year with a new leadership; 0 indicates year with no changes in effective executive	Beck et al. (2001), Goemans, Gleditsch, and Chiozza (2009)
Government crises	Any rapidly developing situation that threatens to bring the downfall of the present regime - excluding situations of revolt aimed at such an overthrow	Banks and Wilson (2014)
Financial crises	Events during which a country's banking sector experiences bank runs, sharp increases in default rates accompanied by large losses of capital that result in public intervention, bankruptcy, or forced merger of financial institutions	Bordo et al. (2001), Reinhart and Rogoff (2009b), Laeven and Valencia (2008, 2012), Jordà, Schularick, and Taylor (2013)
Recessions	Financial recessions: financial crisis within ± 2 years around peak. Normal recessions: all non-financial peaks. Non-financial macro disasters: normal recessions with yearly real p.c. GDP percentage loss > average loss in financial recessions	Algorithm from Bry and Boschan (1971), crisis dating based on Jordà, Schularick, and Taylor (2013) and their sources
GDP	Growth rate of real GDP per capita	Jordà, Schularick, and Taylor (2013) and their sources
Inflation	CPI inflation rate	Jordà, Schularick, and Taylor (2013) and their sources

Table A2: Summary statistics

Variable	Obs.	Mean	Std.Dev.	Min.	Max.
Far-right vote share	1794	5.45	14.5	0.00	99.8
Far-left vote share	1794	5.46	7.01	0.00	34.4
Government vote share	2078	50.7	14.5	12.3	100
Opposition vote share	2078	46.1	14.6	0.00	84.1
Fractionalization of parliament	2510	0.63	0.18	0.00	0.89
No. of parties in parliament	2495	6.26	3.51	1.00	21.0
No. of general strikes	1727	0.22	0.72	0.00	8.00
No. of violent riots	1727	0.81	2.80	0.00	55.0
No. of anti-government demonstrations	1727	0.82	2.99	0.00	60.0
No. of street protest incidents	1727	1.85	5.42	0.00	85.0
No. of major government crises	1727	0.37	0.82	0.00	6.00
Executive turnover dummy	2572	0.29	0.45	0.00	1.00
Financial crises dummy	2900	0.04	0.19	0.00	1.00
Financial recession dummy	2900	0.03	0.17	0.00	1.00
Normal recession dummy	2900	0.12	0.33	0.00	1.00
Non-financial macro disaster dummy	2900	0.02	0.15	0.00	1.00

Notes: Summary statistics refer to the raw data collected for all 20 countries and all years from 1870 to 2014, including non-democratic spells and periods of global war (1914-1918 and 1939-1949). Generally not considered in the empirical analysis of political variables are Austria and Ireland prior to World War I, and Australia prior to 1901 (no independent states). Finland prior to 1917, as an autonomous part of the Russian Empire, is considered.

Appendix B Coding of elections and parliamentary variables

This section lists the sources used to code our archive of election results (vote shares) and parliamentary composition from 1870-2014. The bibliographical details of main sources are shown in the reference list above, while country-specific references are shown in full below.

B.1 Sources of election dates, results and parliamentary composition

The election data come from the following three main sources:

- D/M: Döring and Manow (2012)
- M/R: Mackie and Rose (1974)
- N/S: Nohlen and Stöver (2010)

Detailed election data sources per country:

Australia: Elections from 1901-2013: D/M. – **Austria:** 1919-1930: M/R. 1945-2013: D/M. – **Belgium:** 1870.1-1939: M/R. 1946-2014: D/M. – **Canada:** 1872-1940: M/R. 1945-2011: D/M. – **Denmark:** 1872-1873: Skov, Kaare. 1999. *Demokratiets Danmarkshistorie – Gennem 150 år*. Dartmouth: Parliamentary Research Services. 1885-1935: M/R. 1945-2010: D/M. – **United States:** 1870-1918: Dubin, Michael J. 1998. *United States Congressional Elections, 1788-1997: The Official Results of the Elections of the 1st through 105th Congresses*. Jefferson: McFarland. 1920-2014: Office of the Clerk of the U.S. House of Representatives. 2014. *Election Statistics*. Available at www.history.house.gov/institution/election-statistics/election-statistics/.

An overview of all elections in our 20-country sample spanning the years from 1870-2014 is provided in the table below. Altogether, we identified 751 elections, but we could not find sufficient data for 32 of these (in round brackets), so the final sample of coded elections includes 719 events.

Table B1: Parliamentary elections 1870-2014

Notes: () = no data available [] = monarchy/dictatorship * = two elections in that year.

The table provides a chronology of elections from 1870-2014 by country. We include all general elections to the national parliament, but not sub-national or presidential elections. In the case of a bicameral legislative, we only consider results from the lower legislative chamber. This means that we focus on the following results: AUS: House of Representatives (lower house); AUT: National Council (lower house); BEL: Chamber of Representatives (lower house); CAN: House of Commons (lower house); CHE: National Council (lower house); DEU: Bundestag (until 1945 Reichstag) (unicameral); DNK: Folketing (until 1953 lower house, since then unicameral); ESP: Congress of Deputies (lower house); FIN: Eduskunta (unicameral); FRA: National Assembly (until 1946 Chamber of Deputies) (lower house); GBR: House of Commons (lower house); GRC: Hellenic Parliament (unicameral, bicameral from 1927-1935); IRL: Dáil Éireann (lower house); ITA: Chamber of Deputies (lower house); JPN: House of Representatives (lower house). NLD: Tweede Kamer (lower house); NOR: Storting (unicameral); PRT: Assembly of the Republic (unicameral, bicameral from 1915-1925); SWE: Riksdag (unicameral); USA: House of Representatives (lower house).

B.2 Coding of far-right and far-left parties

This section lists the sources used to classify parties as far-right or far-left in the period from 1919-2014. For the interwar period (1919-1938) we follow the classification in de Bromhead, Eichengreen and O'Rourke (2012) and their main source Capoccia (2001), unless otherwise stated. All remaining sources for our post-World War II classification by country are listed below. The coding result with a full list of far-left and far-right parties is shown in Table B2.

Australia: Davis, Rex, and Robert Stimpson. 1998. Disillusionment and Disenchantment at the Fringe: Explaining the Geography of the One Nation Party Vote at the Queensland Election. *People and Place* (6)3: 69–82. – Gouttman, Rodney. 2001. Pernicious Vision: Challenge from within Australia's Extreme Right. *Australian Journal of Jewish Studies* 15: 46–63. – Grant, Bligh. 1997. Pauline Hanson. One Nation and Australian Politics. University of New England Press. – Leach, Michael, Geoff Stokes, and Ian Ward. 2000. The Rise and Fall of One Nation. University of Queensland Press. – **Austria:** Carter, Elisabeth. 2001. The Extreme Right in Austria. An Overview. EREPS. – Carter, Elisabeth. 2005. The Extreme Right in Western Europe. Manchester, New York: Manchester University Press. – Howard, Marc Morjé. 2001. Can Populism Be Suppressed in a Democracy? Austria, Germany, and the European Union. *East European Politics and Societies* (15)1: 18–32. – McGann, Anthony, and Herbert Kitschelt. 2005. The Radical Right in The Alps: Evolution of Support for the Swiss SVP and Austrian FPÖ. *Party Politics* 11(29): 147–171. – **Belgium:** Art, David. 2008. The Organizational Origins of the Contemporary Radical Right: The Case of Belgium. *Comparative Politics* 40(4): 421–440. – Craeybeckx, Jan, Els Witte, and Alain Meynen. 2010. Political History of Belgium: From 1830 Onwards. VUB University Press. – Swyngedouw, Mark. 2009. Country Report Belgium. In: Bertelsmann Stiftung (ed.): *Strategies for Combating Right-Wing Extremism in Europe* (Gütersloh: Verlag Bertelsmann-Stiftung 2009): 59–80. – **Canada:** Barrett, Stanley. 1989. The Far Right in Canada. In: C.E.S. Franks (ed.): *Dissent and the State* (Toronto: University of Toronto Press 1989): 224–246. Oxford University Press: 224–246. – Communist Party of Canada (1982). *Canada's Party of Socialism*. Toronto: Progress Books. – Parent, Richard A., and James O. Ellis III. 2014. Right-Wing Extremism in Canada. TSAS Working Paper Series No. 14-03. – Ross, Jeffrey Ian. 1992. Contemporary Radical Right-Wing Violence in Canada: A Quantitative Analysis. *Terrorism and Political Violence* 4(3): 72–101. – **Denmark:** Jungar, Ann-Cathrine, and Anders Ravik Jupskas. 2014. Populist Radical Right Parties in the Nordic Region: A New and Distinct Party Family? *Scandinavian Political Studies* 37(3): 215–238. – Meret, Susi. 2009. Country Report Denmark. In: Bertelsmann Stiftung (ed.): *Strategies for Combating Right-Wing extremism in Europe* (Gütersloh: Verlag Bertelsmann-Stiftung 2009): 81–126. – Rydgren, Jens. 2004. Explaining the Emergence of Radical Right-Wing Populist Parties: The Case of Denmark. *West European Politics* 27(3): 474–502. – **Finland:** For the interwar years we deviate from de Bromhead, Eichengreen and O'Rourke (2012) in that we do not code the Finnish “National Coalition” as far-right but rather as centre-right (Lane and Ersson 2008, p. 260, table 8.7). While the party was in a one-time electoral alliance with the far-right “Patriotic People's Movement” (1933 elections), we can distinguish between the two and count the “Patriotic People's Movement's” vote share separately. Other sources include Arter, David. 2010. The Breakthrough of Another West European Populist Radical Right Party? The Case of the True Finns. *Government and Opposition* 45(4): 484–504. – Jungar, Ann-Cathrine, and Anders Ravik Jupskas. 2014. Populist Radical Right Parties in the Nordic Region: A New and Distinct Party Family? *Scandinavian Political Studies* 37(3): 215–238. – Nordensvard, Johan, and Markus Ketola. 2014. Nationalist Reframing of the Finnish

and Swedish Welfare States – The Nexus of Nationalism and Social Policy in Far-right Populist Parties. *Social Policy & Administration* (49)3: 356-375. – **France:** Camus, Jean-Yves. 2009. Country Report France. In: Bertelsmann Stiftung (ed.): *Strategies for Combating Right-Wing Extremism in Europe* (Gütersloh: Verlag Bertelsmann-Stiftung 2009): 127-178. – Davies, Peter. 1999. *The National Front in France: Ideology, Discourse and Power*. New York: Routledge. – Marcus, Jonathan. 1995. *The National Front and French Politics*. London: Macmillan. – Shields, James. 2007. *The Extreme Right in France: From Pétain to Le Pen*. New York: Routledge. – Simmons, Harvey. 1996. *The French National Front: The Extremist Challenge to Democracy*. Boulder: Westview Press. – **Germany:** Bulmer, Simon. 2014. Germany and the Eurozone Crisis: Between Hegemony and Domestic Politics. *West European Politics* 37(6): 1244-1263. – Michael, George, and Michael Minkenberg. 2007. A Continuum for Responding to the Extreme Right: A Comparison between the United States and Germany. *Studies in Conflict & Terrorism* 30(12): 1109-1123. – Schellenberg, Britta. 2009. Country Report Germany. In: Bertelsmann Stiftung (ed.): *Strategies for Combating Right-Wing Extremism in Europe*. (Gütersloh: Verlag Bertelsmann-Stiftung 2009): 179-248. Stöss, Richard. 1991. *Politics Against Democracy: Extreme Right in West Germany* (German Studies Series). Oxford: Berg Publishers. – **Greece:** Davies, Peter, and Derek Lynch. 2002. *The Routledge Companion to Fascism and the Far Right*. London: Routledge. – Ellinas, Antonis. 2013. 	L	Democratic Unitarian Coalition, Left Bloc, Left Revolutionary Front, People's Democratic Union, People's Socialist Front, Portuguese Communist Party*, Portuguese Labour Party, Portuguese Workers' Communist Party, Revolutionary Socialist Party, United People Alliance, Workers Party of Socialist Unity
SWE	R	National Socialist Party*, National League of Sweden*, New Democracy, Sweden Democrats
	L	Communist Party of Sweden*, The Left Party
USA	R	No electorally successful parties identified
	L	No electorally successful parties identified

Notes: *Parties with an asterisk are those participating in elections between 1919-1938. Some of these (e.g., French Communist Party) still exist today, some have dissolved, some were banned (e.g., Communist Party of Germany), some were merged into new parties, or changed their name over time (e.g., Flemish Nationalists to Flemish Block to Flemish Interest). In our analysis we always calculate the vote share of all *then-current* far-right and far-left parties.

B.3 Coding of government and opposition parties

This section lists the sources used to classify parties into government and opposition. The classification for the post-World War II period mainly follows Döring and Manow (2012) (D/M). The remaining historical and country-specific sources are listed below:

Australia: 1901-2013: D/M. – **Austria:** 1919-1930: Website of the Austrian government. Available at www.parlament.gv.at/WWER/BREG/REG. 1945-2013: N/S. **Belgium:** 1870.2-1939: Website of the Belgian government. Available at www.premier.fgov.be; 1946-2014: D/M. – **Canada:** 1872-1940: Privy Council Office. 2013. A Guide to Canadian Ministries since Confederation. Ottawa. Available at www.pco-bcp.gc.ca/mgm; 1945-2011: D/M. – **Denmark:** 1901-1943: Website of the Danish government. Available at www.stm.dk; 1945-2011: D/M. – **Finland:** 1919-1924: The Finnish Government. 2014. Government and Ministers since 1917. Helsinki. Available at www.valtioneuvosto.fi/tietoa/historiaa/hallitukset-ja-ministerit; 1927-2011: D/M. – **France** 1871-1936: Website of the French government. Available at www.gouvernement.fr; 1945-2012: D/M. – **Germany:** 1919-1932.2: Lothar Gall, and Michael Hollman. 2009. Reich Chancellery Files: Weimar Republic Edition (Online Version). Available at www.bundesarchiv.de/aktenreichskanzlei/1919-1933/0000/index.html; 1949-2013: D/M. – **Greece:** 1889-1964: Henisz, Witold. 2000. The Institutional Environment for Economic Growth. Economics and Politics. 12(1): 1-31; 1974-2012.2: D/M. – **Ireland:** 1918-1943: Website of the Irish government. Available at www.taoiseach.gov.ie/eng/historical_information/history_of_government; 1944-2011: D/M. – **Italy:** 1874-1921: Henisz, Witold. 2000. The Institutional Environment for Economic Growth. Economics and Politics. 12(1): 1-31; 1946-2013: D/M. – **Japan:** 1946-2014: D/M. – **Netherlands:** 1888-1937: Website of the Dutch government. Available at www.government.nl; 1946-2012: D/M. – **Norway:** 1885-1936: Government Administration Services. Information from the Government and the Ministries. Norway's Governments since 1814. Available at www.regjeringen.no/en/the-government/previous-governments; 1945-2013: D/M. – **Portugal:** 1911-1925: Henisz, Witold. 2000. The Institutional Environment for Economic Growth. Economics and Politics. 12(1): 1-31; 1975-2011: D/M. – **Spain:** 1873, 1931-1936: Henisz, Witold. 2000. The Institutional Environment for Economic Growth. Economics and Politics. 12(1): 1-31; 1977-2011: D/M. – **Sweden:** 1917-1940: Website of the Swedish government. Available at www.government.se/sb/d/576; 1944-2014: D/M. – **Switzerland:** 1872-1917: The Federal Authorities of the Swiss Confederation. All Federal Councillors since 1848. Bern. Available at www.admin.ch/gov/en/start/federal-council.html; 1919-2011: D/M. – **United Kingdom:** 1874-1935: Cook, Chris, and Brendan Keith. 1984. British Historical Facts, 1830-1900. Palgrave Macmillan, Butler, David. 2000. Twentieth Century British Political Facts, 1900-2000. Palgrave Macmillan, Henisz, Witold. 2000. The Institutional Environment for Economic Growth. Economics and Politics. 12(1): 1-31; 1945-2010: D/M. – **United States:** 1870-2014: United States government. Website of the White House. Available at www.whitehouse.gov/about/presidents.

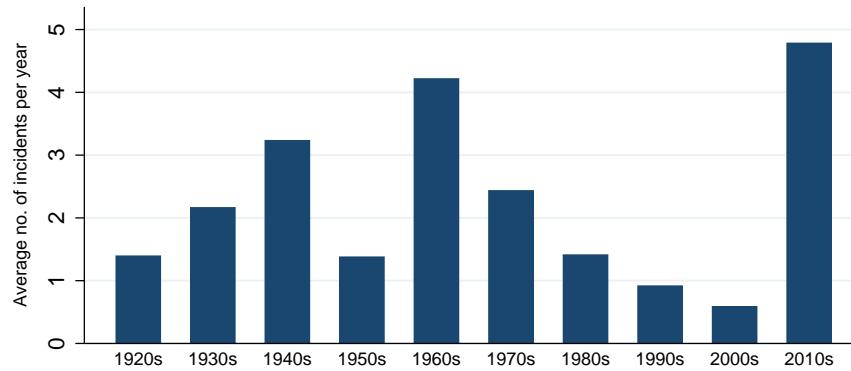

B.4 Coding the fractionalization measure

To measure parliamentary fractionalization it is essential to define what a party is. This is not always straightforward. To define parties we follow the approach used by Beck et al. (2001) and apply it to all parliaments since 1870. Specifically, we use the following coding rules:

- We split up party umbrellas and electoral fronts and count the parties individually if one or more of the following conditions are met: (1) the parties in the front compete for seats, (2) two or more parties within the front put forward their own presidential/premier candidates, and/or (3) the sources indicate that cabinet positions have been distributed among members of the different parties forming the front. If none of these are true, the front is recorded as a single party. If the sources only provide seats for the front, we regard the front as one party. In case of ambiguities, the front is considered to be one party.
- If parties have several wings based on language or ethnic divisions (e.g. Belgium), the wings are treated as separate or united depending on how the voting results and seats are reported in statistical sources. If the seats are broken down by wing they are classified as separate parties; if seats are only reported for the overall party, we regard it as one party.
- Independent deputies are treated as if they were individual parties with one seat each. This applies for the fractionalization measure, but not for our variable that represents the number of parties in the legislature.
- Unless otherwise stated parties and independent deputies from autonomous or semi-autonomous territories are included when sources indicate their presence in the parliament (e.g., France or Denmark).

Appendix C Coding of street protest variables

Figure C1: Street protests: variation over time

Notes: The figure shows the number of street protest incidents per year, averaged over the decades from the 1920s to the 2010s. Note that the 2010s column in the lower panel refers only to the years 2010-2012.

Appendix D Financial crises and recession dates

Table D1: Financial crisis events, 1870-2014

Australia	1893	1989							
Austria	<i>1873</i>	1924	<i>1929</i>	2008					
Belgium	<i>1870</i>	1885	1925	<i>1931</i>	<i>1939*</i>	2008			
Canada	<i>1873</i>	1907	<i>1923</i>						
Denmark	1877	<i>1885</i>	1908	<i>1921</i>	1931	1987	2008		
Finland	1878	1900	<i>1921</i>	1931	1991				
France	1882	<i>1889</i>	1907	1930	2008				
Germany	<i>1873</i>	1891	<i>1901</i>	1907	1931	2008			
Greece	1931	1991	2008						
Ireland	2008								
Italy	1873	<i>1887</i>	<i>1893</i>	1907	<i>1921</i>	1930	<i>1935*</i>	1990	2008

United States	1895	1913	1918	1937	1944	1957	1981	

Notes: The table shows a sub-sample of non-financial macro-economic disasters from the normal recessions listed in Table D2. Non-financial macro-economic disasters are defined as normal recessions where the yearly real p.c. GDP percentage loss is higher than the average in financial crisis recessions. Thresholds are calculated separately for the pre-World War II sample (-3.35%) and the post-World War II sample (-2.55%).

Appendix E Local projections

Table E1: Local projections of government vote shares

(a) Full sample	Year 1	Year 2	Year 3	Year 4	Year 5
Financial recession	-2.16 (1.76)	-3.35 (2.41)	-0.88 (2.90)	0.59 (3.28)	-1.48 (2.77)

Observations	1180	1159	1138	1118	1098

Notes: *** Significant at .01. ** Significant at .05. * Significant at .1. Robust standard errors (clustered by country) in parentheses. Results correspond to local projections of cumulative change in 100 times the logged variable relative to peak for years 1–5 of the financial recession (first row), normal recession (second row), and non-financial macro disaster (third row). (a) 1870–2014, (b) 1870–1938, (c) 1950–2014. World War I (1914–1918) and World War II (1939–1949) excluded. Financial = normal (disaster) tests the null that coefficients for each type of recession are the same for the intercept terms in the first and second (third) rows. In each case the p-value of the test is provided. The controls are contemporaneous and 1-year lagged values of the growth rate of GDP per capita and the CPI inflation rate at peak (coefficients not reported). See text.

Table E2: Local projections of opposition vote shares

Notes: *** Significant at .01. ** Significant at .05. * Significant at .1. Robust standard errors (clustered by country) in parentheses. Results correspond to local projections of cumulative change in 100 times the logged variable relative to peak for years 1–5 of the financial recession (first row), normal recession (second row), and non-financial macro disaster (third row). The top panel (a) covers the years 1870–2014, the middle panel (b) covers the years 1870–1938, and the bottom panel (c) covers the years 1950–2014. World War I years (1914–1918) and World War II years (1939–1949) are excluded. Financial = normal tests the null that coefficients for each type of recession are the same for the intercept terms in the first and second rows. Financial = disaster tests the null that coefficients for each type of recession are the same for the intercept terms in the first and third rows. In each case the p-value of the test is provided. The controls are contemporaneous and 1-year lagged values of the growth rate of GDP per capita and the CPI inflation rate at peak (coefficients not reported). See text.

Appendix F The reform process after crises: veto players

This section describes Tsebelis' (2002) Veto Player Index, as well as the application of the index in our analysis. Tsebelis (2002) defines a veto player as any individual (e.g., a president or a strong party) or collective (e.g., a parliament or a weak party) political actor that can veto reforms. More specifically, the Veto Player Index, for a given country and year, captures (a) the number of such veto players, (b) their maximum ideological distance from each other (right/left dimension), and (c) the internal coherence of individual players.

The index ranges from 0 to 12 and increases in the number of veto players, in the degree of diverging preferences among them, and/or if there is less internal coherence among the set of veto players. According to Tsebelis (2002), higher index values imply more difficulties in policy-making and a reduced chance for implementing reforms.

Figure F1 plots local projections on the evolution of the veto player index post-crisis, using Tsebelis' (2002) data for 18 countries in the post-World War II period (the data cover only the years from 1945 to 2000 and exclude Greece and the United States).

Figure F1: Veto Player Index (local projections): financial crisis recessions

Notes: Each path shows local projections of the cumulative change relative to peak for years 1–5 of the recession/recovery period. The red line refers to the average path in financial crisis recessions and the shaded region is a 90% confidence interval. The controls are contemporaneous and 1-year lagged values of the growth rate of GDP per capita and the CPI inflation rate at peak. The panel covers the years from 1950 to 2000. Table D2 shows the recessions included. The dependent variable is Tsebelis' (2002) Veto Player Index.

The estimates show that the index increases by a cumulative 37% in year 2 after the crisis and is back to the pre-crisis level by year 4. This suggests that political constraints become significantly more intense, making it harder to govern and to get reforms underway.

For robustness, we also use the Political Constraint Index III by Henisz (2000), which resembles the index by Tsebelis, but measures the preferences of – and the alignment across – three government branches (executive, lower house, upper house). Henisz' measure is bound between 0 and 1, with higher values indicating more political constraints. Similar to Figure F1, we find a significant post-crisis increase in this index, although the magnitude is smaller compared to the Tsebelis data. The results are available upon request.
